## Abstract

The article deals with the problem of finding vertex-minimal graphs with a given automorphism group. We exhibit two undirected 16-vertex graphs having automorphism groups  $A_4$  and  $A_5$ . It improves Babai's bound for  $A_4$  and the graphical regular representation bound for  $A_5$ . The graphs are constructed using projectivisation of the vertex-face graph of the icosahedron.

*Keywords:* graph, icosahedron, hemi-icosahedron, automorphism group, alternating group  
*Mathematics Subject Classification :* 05C25, 05E18, 05C35.

This article addresses a problem in graph representation theory of finite groups - finding undirected graphs with a given automorphism group and minimal number of vertices. Denote by  $\mu(G)$  the minimal number of vertices of undirected graphs having automorphism group isomorphic to  $G$ ,  $\mu(G) = \min_{\Gamma: Aut(\Gamma) \simeq G} |V(\Gamma)|$ . It is known [1] that  $\mu(G) \leq 2|G|$ , for any finite group  $G$  which is not cyclic of order 3, 4 or 5. See Babai [2] for an exposition of this area. There are groups which admit a graphical regular representation, for such groups  $\mu(G) \leq |G|$ . For some recent work see [4].

For alternating groups  $A_n$   $\mu(A_n)$  is known for  $n \geq 13$ , see Liebeck [6]. If  $n \equiv 0$  or  $1 \pmod{4}$ , then  $\mu(A_n) = 2^n - n - 2$ . Additionally, for  $n \geq 5$   $A_n$  admits a graphical regular representation, see [8]. Thus for  $A_5$  the best published estimate until now seemed to be  $\mu(A_5) \leq 60$ .

In this paper we exhibit graphs  $\Gamma_i = (V, E_i)$ ,  $i \in \{4, 5\}$ , such that  $|V| = 16$  and  $Aut(\Gamma_i) \simeq A_i$ .

Received: 13 February 2019, Revised: 17 February 2020, Accepted: 1 March 2020.

$\Gamma_4$  (also denoted  $\Xi_I$ ) improves Babai’s bound for  $A_4$ .  $\Gamma_5$  (also denoted  $\Pi_I$ ) has fewer vertices than the graphical regular representation of  $A_5$ .  $\Gamma_5$  is listed in [3] together with the order of its automorphism group. The new graphs are based on projectivisation of the vertex-face incidence relation of the regular icosahedron.

We use standard notation for undirected graphs, see Diestel [5]. A bipartite graph  $\Gamma$  with vertex partition sets  $V_1$  and  $V_2$  is denoted as  $\Gamma = (V_1, V_2, E)$ . Given a polyhedron  $P$ , we denote its vertex, edge and face sets as  $V = V(P)$ ,  $E = E(P)$  and  $F = F(P)$ , respectively. We can think of  $P$  as the triple  $(V, E, F)$ . If  $S$  is a subset of  $\mathbb{R}^3$  not containing the origin, then its image under the projectivisation map to  $P(\mathbb{R}^3)$  is denoted by  $\pi(S)$  or  $[S]$ ,  $[S] = \bigcup_{x \in S} [x]$ .

**1. Main results**

In this section we define objects used for our construction - projective vertex-face graphs. We prove that the automorphism group of the projective vertex-face graph of the regular icosahedron is  $A_5$ . We further show that after adding three extra edges we get a graph with the automorphism group  $A_4$ .

*1.1. Vertex-face graphs of polyhedra*

**Definition 1.1.** Let  $P = (V, E, F)$  be a polyhedron. An undirected bipartite graph  $\Gamma_P = (V, F, I)$  is the **vertex-face graph of  $P$**  if  $v \sim f$  iff  $v \in V$ ,  $f \in F$  and  $v \in f$ . In other words,  $\Gamma_P$  corresponds to the vertex-face incidence relation in  $V \times F$ .

**Definition 1.2.** Let  $S = (V, E, F)$  be a centrally symmetric polyhedron. Let  $S$  be positioned in  $\mathbb{R}^3$  so that its center is at  $(0, 0, 0)$ . We call the undirected bipartite graph  $\Pi_S = ([V], [F], I_p)$  **projective vertex-face graph** if for any  $v_p \in [V]$ ,  $f_p \in [F]$  we have  $v_p \sim f_p$  iff  $v \in f$  for some  $v \in \pi^{-1}(v_p)$  and  $f \in \pi^{-1}(f_p)$ .

*1.2. Projective vertex-face graph of the icosahedron and  $A_5$*

Let  $I = (V, E, F)$  be the regular icosahedron. Define  $\Gamma_5 = \Pi_I$ , it is shown in Fig.1, an adjacency matrix of  $\Pi_I$  is given in Appendix A.  $\Pi_I$  can be interpreted in terms of the hemi-icosahedron, see [7].

Fig.1. -  $\Pi_I$ .

**Proposition 1.1.** *Let  $I$  be the regular icosahedron. Then  $Aut(\Pi_I) \simeq A_5$ .*

*Proof.* We prove that  $Rot(I) \simeq Aut(\Pi_I)$  in two steps. First we show that there is a subgroup in  $Aut(\Pi_I)$  isomorphic to  $Rot(I)$  - the group of rotational symmetries of  $I$ , rotations of  $\mathbb{R}^3$  preserving  $V$  and  $E$ . It is known that  $Rot(I) \simeq A_5$ . There is an injective group morphism  $f : Rot(I) \xrightarrow{f_1} Aut(\Gamma_I) \xrightarrow{f_2} Aut(\Pi_I)$ .  $f_1 : Rot(I) \rightarrow Aut(\Gamma_I)$  maps every  $\rho \in Rot(I)$  to  $f_1(\rho) \in Aut(\Gamma_I)$  which is the permutation of  $V \cup F$  induced by  $\rho$ :  $f_1(\rho)(x) = \rho(x)$  for any  $x \in V \cup F$ . Rotations of  $I$  preserve the vertex-face incidence relation and  $f_1$  is a group morphism.  $f_2 : Aut(\Gamma_I) \rightarrow Aut(\Pi_I)$  maps every  $\varphi \in Aut(\Gamma_I)$  to  $\varphi_P \in Aut(\Pi_I)$  defined by the rule  $\varphi_P([x]) = [\varphi(x)]$  for any  $x \in V(\Gamma_I)$ . Projectivization and composition commute therefore  $f_2$  is a group morphism.  $f$  is injective since there is no nontrivial rotation of  $I$  sending each vertex to another vertex in the same projective class.

In the second step we prove that  $|Aut(\Pi_I)| \leq 60$  by a counting argument. Every vertex  $v \in [V]$  is contained in a subgraph  $\sigma(v)$  shown in Fig.2.

Fig.2. -  $\sigma(v)$ .

All  $\Pi_I$ -vertices in  $[V]$  have degree 5, all  $\Pi_I$ -vertices in  $[F]$  have degree 3. It follows that  $[V]$  and  $[F]$  both are unions of  $Aut(\Pi_I)$ -orbits.  $v$  can be mapped by a  $\Pi_I$ -automorphism in at most 6 possible ways. After fixing the image of  $v$  it follows by  $Aut(\Pi_I)$ -invariance of  $[V]$  that the subgraph  $\sigma(v)$  can be mapped in at most 10 ways. Any permutation of  $[V]$  by an automorphism determines a unique permutation of  $[F]$ . Thus  $|Aut(\Pi_I)| \leq 60$ . We have proved that  $Aut(\Pi_I) = f(Rot(I)) \simeq A_5$ . □

*Remark 1.1.* A graph isomorphic to  $\Pi_I$  is listed without discussion of its construction and automorphism group in [3] as ET16.5.

### 1.3. A modification of the projective vertex-face graph of the icosahedron and $A_4$

Since  $A_5$  has subgroups isomorphic to  $A_4$ , we can try to modify  $\Pi_I$  so that the automorphism group of the modified graph is isomorphic to  $A_4$ . We find generators for a subgroup  $H \leq Rot(I)$ , such that  $H \simeq A_4$ , and add three extra edges to  $\Pi_I$  which are permuted only by elements of  $H$ .

Denote by  $I_1$  the polyhedral (1-skeleton) graph of  $I$ ,  $Aut(I_1) \simeq Sym(I) \simeq A_5 \times \mathbb{Z}_2$ .

**Proposition 1.2.** *Choose a 6-subset of vertices  $W = \{O, A, B, C, D, E\} \subseteq V(I)$  such that  $I_1[W]$  is isomorphic to the 5-wheel, see Fig.3.*

Fig.3. -  $I_1[W]$ .

Define an undirected graph  $\Gamma_4 = \Xi_I = ([V] \cup [F], I_p \cup J)$  by adding three edges to  $\Pi_I$ :  $J = \{[A] \sim [C], [B] \sim [O], [D] \sim [E]\}$ , see Fig.4, Fig.5 and Appendix B. Then  $Aut(\Xi_I) \simeq A_4$ .

Fig.4. - the extra edges.

Fig.5. -  $\Xi_I$ .

*Proof.* Consider the subgroup  $H = \langle a, b \rangle \leq Rot(I)$  generated by two rotations:  $a$  - a rotation of order 2 around the line passing through the center of the edge  $OB$  and the center of  $I$ ,  $b$  - a rotation of order 3 around the line passing through the center of the face  $OCD$  and the center of  $I$ . We prove that  $H \simeq A_4$  and  $f(H) = Aut(\Xi_I)$  where  $f$  is as in Proposition 1.1.

To prove that  $H \simeq A_4$  we investigate subgroups of  $A_5$  generated by two elements of order 2 and 3. If  $H' = \langle a', b' \rangle \leq A_5$ ,  $ord(a') = 2$ ,  $ord(b') = 3$ , then there are 3 possibilities for the isomorphism type of the functional graph ("cycle type") of the pair  $(a', b')$ :  $(a_1, b_1) = ((12)(34), (345))$ ,  $(a_2, b_2) = ((12)(34), (134))$  or  $(a_3, b_3) = ((12)(34), (135))$ . It can be checked that  $\langle a_1, b_1 \rangle \simeq \Sigma_3$ ,  $\langle a_2, b_2 \rangle \simeq A_4$ ,  $\langle a_3, b_3 \rangle \simeq A_5$ . Additionally,  $ord(a_1 b_1) = 2$ ,  $ord(a_2 b_2) = 3$ ,  $ord(a_3 b_3) = 5$ . Now, in our case  $ord(ab) = 3$ , thus  $H = \langle a, b \rangle \simeq \langle a_2, b_2 \rangle \simeq A_4$ .

Next we prove that  $Aut(\Xi_I) = f(H)$ . Note that  $O, A, B, C, D, E$  in Fig.3 and Fig.4 represent  $[V]$ .

First we prove that  $f(H) \leq Aut(\Xi_I)$ .  $\Xi_I$  differs from  $\Pi_I$  by three extra edges. Elements of  $f(H)$  permute  $\Pi_I$ -edges so we only need to check that they permute the new edges. The restrictions

of  $f(a)$  and  $f(b)$  to  $[V]$  are, respectively,  $([O][B])$  and  $([O][C][D])([A][E][B])$  (in cycle notation). It follows that  $f(b)$  cyclically permutes the three extra edges and  $f(a)$  fixes them.

To prove that  $Aut(\Xi_I) \leq f(H)$  we observe that only  $[F]$ -type vertices have degree 3 in both  $\Pi_I$  and  $\Xi_I$ , only  $V$ -type vertices have degree 5 in  $\Pi_I$ . Thus any  $Aut(\Xi_I)$ -element as a permutation of  $[V] \cup [F]$  belongs to  $Aut(\Pi_I)$  and thus is the  $f$ -image of a  $Rot(I)$ -element. We show that for any rotation  $r' \in Rot(I) \setminus H$ ,  $f(r')$  does not permute the three extra edges and thus  $f(r') \notin Aut(\Xi_I)$ . We have that  $Rot(I) = \langle a, b, c \rangle$  where  $c$  is any rotation of order 5. Since  $|Rot(I) : H| = 5$  it follows that any element of  $Rot(I)$  is in form  $c^n h$  where  $h \in \langle a, b \rangle = H$ . Let  $c$  be the rotation around the line passing through the center of  $I$  and  $O$  corresponding to the vertex permutation  $(ABCDE)$ . The edge  $[O] \sim [B]$  is the only extra edge having  $[O]$  as a vertex, all edges from  $[O]$  are rotationally permuted by  $f(c^n)$ , see Fig.4. It follows that nontrivial elements  $f(c^n)$  do not permute the three extra edges in  $\Xi_I$ .  $\square$

*Remark 1.2.* If  $D$  is the dodecahedron then  $\Pi_D \simeq \Pi_I \simeq A_5$ .

## 2. Appendices

*A - An adjacency matrix of  $\Pi_I$*

*Remark 2.1.* In the standard ordering vertices  $\{1, \dots, 10\}$  correspond to  $[F]$  and vertices  $\{11, \dots, 16\}$  correspond to  $[V]$ .
